The most widely used experimental stress-analysis technique in industry today, particularly under working conditions, is that of strain gauges. Whilst a number of different types of strain gauge are commercially available, this section will deal almost exclusively with the electrical resistance type of gauge introduced in 1939 by Ruge and Simmons in the United States.

Experimental stress analysis of whole bones, implants, and whole bone – implant constructs is an important approach in orthopaedic biomechanics. High stresses in whole bones and implants may cause mechanical failure, but low stresses in whole bone may cause “ stress shielding, ” which leads to bone atrophy, bone resorption, and implant loosening.

Stress is a measure of the force per unit area acting on a plane passing through the point of interest in a body. The above geometrical data (the strains) will be multiplied by material properties to define a new physical quantity, the stress, which is directly proportional to the strains.

The brittle-lacquer technique of experimental stress analysis relies on the failure by cracking of a layer of a brittle coating which has been applied to the surface under investigation. The coating is normally sprayed onto the surface and allowed to air- or heat-cure to attain its brittle properties.
