Lattice Boltzmann methods (LBM), originated from the lattice gas automata (LGA) method (Hardy-Pomeau-Pazzis and Frisch-Haslach-Pomeau models), is a class of computational fluid dynamics (CFD) methods for fluid simulation. Instead of solving the Navier – Stokes equations directly, a fluid density on a lattice is simulated with streaming and collision (relaxation) processes.

The lattice-Boltzmann method has been applied to many complex flow problems in the past[1-5]. However, its application to aer propulsion applications has not been reported. To apply the lattice-Boltzmann method to aer propulsion related flow problems, more specifically, to turbomachinery flow simulations, there are two major hurdles to be overcome.

The OpenLB project provides a C++ package for the implementation of lattice Boltzmann methods that is general enough to address a vast range of transport problems, e.g. in computational fluid dynamics. The source code is publicly available and constructed in a well readable, modular way. This enables for a fast implementation of both simple academic test problems and advanced engineering applications.

The lattice Boltzmann method is a powerful technique for the computational modeling of a wide variety of complex fluid flow problems including single and multiphase flow in complex geometries. It is a discrete computational method based upon the Boltzmann equation. It considers a typical volume element of fluid to be composed of a collection of particles that are represented by a particle velocity distribution function for each fluid component at each grid point.
